DISTINGUISHING MAXIMAL ORDERS OF QUATERNION ALGEBRAS BY THEIR SHORT ELEMENTS

I. CHEVYREV AND S. D. GALBRAITH

ABSTRACT. Let $\mathcal{O}$ be a maximal order in the quaternion algebra B_p ramified at p and ∞. Our main result is that, under certain conditions on a rank three sublattice $\mathcal{O}^T$ of $\mathcal{O}$, the order $\mathcal{O}$ is effectively characterized by the three successive minima and two other short vectors of $\mathcal{O}^T$. The desired conditions turn out to hold whenever the j-invariant $j(\mathcal{O})$ of the elliptic curve associated to the maximal order $\mathcal{O}$ lies in $\mathbb{F}_p$. We introduce Algorithm 1, which, given a maximal order $\mathcal{O}$, computes $j(\mathcal{O})$ using the reduction of Hilbert class polynomials to $\mathbb{F}_p$, and we use Theorem 1 to prove that Algorithm 1 terminates within running time $O(p^{1+\varepsilon})$ under the aforementioned conditions. As an application we present Algorithm 2, with running time $O(p^{2.5+\varepsilon})$, which is a more efficient alternative to Cerviño's algorithm to simultaneously match all maximal order types with their associated j-invariants.

CONTENTS

1. INTRODUCTION

Let p be a prime and E a supersingular elliptic curve over $\mathbb{F}_{p^2}$. Then $\mathrm{End}(E)$ is a maximal order in the quaternion algebra B_p ramified exactly at p and ∞ (all notation and definitions are explained in Section 2). A special case of interest is when E is defined over $\mathbb{F}_p$, in which case $\mathrm{End}(E)$ contains an element π such that $\pi^2 = -p$.

Ibukiyama [11] has given an explicit description of all such maximal orders containing $\sqrt{-p}$. For example, let $p \equiv 1 \pmod 4$ and let $\mathcal{O}$ be a maximal order in B_p. Then there is a prime $q \equiv 3 \pmod 8$ such that $(\frac{-q}{p}) = -1$, and an isomorphism $\phi : B_p \to \mathbb{Q} + \mathbb{Q}i + \mathbb{Q}j + \mathbb{Q}k$ where $i^2 = -p$, $j^2 = -q$ and $k = ij = -ji$, such that $\phi(\mathcal{O}) \cong \mathbb{Z} + \mathbb{Z}(1+j)/2 + \mathbb{Z}(i+k)/2 + \mathbb{Z}(rj+k)/q$ where r is any integer such that $q \mid (r^2 + p)$.

Consider the $\mathbb{Z}$-module $\mathcal{O}^T = \{2x - \mathrm{Tr}(x) : x \in \mathcal{O}\}$ of rank 3 . Note that $y \in \mathcal{O}^T$ implies $\mathrm{Tr}(y) = 0$ and so $\mathcal{O}^T$ is a subset of the pure quaternions. Fix a $\mathbb{Z}$-module basis $\{\omega_1, \omega_2, \omega_3\}$ for $\mathcal{O}^T$ and consider the ternary quadratic form $Q(x, y, z) = \mathrm{Nr}(x\omega_1 + y\omega_2 + z\omega_3)$ giving a norm on $\mathcal{O}^T$. Kaneko [12] has shown, in the special case where $\sqrt{-p} \in \mathcal{O}^T$, that there is an element $x \in \mathcal{O}^T$ of norm at most $\frac{4}{\sqrt{3}}\sqrt{p}$. Let $\mathcal{O}'$ be another maximal order in the same quaternion algebra B_p and let Q' be the ternary form associated with $\mathcal{O}'$. A natural question is whether Q determines $\mathcal{O}$. In other words, if Q' is equivalent to Q in the sense of quadratic forms then is $\mathcal{O}'$ isomorphic to $\mathcal{O}$? We will show that this is the case. Indeed, our main result (Theorem 1) is much stronger: It states that if the forms Q and Q' have the same successive minima, plus some other mild conditions, then $\mathcal{O} \cong \mathcal{O}'$, and hence Q and Q' are equivalent. Schiemann [15] has shown

that two ternary quadratic forms are determined by their theta series. Our result may be viewed as a strong form of Schiemann's theorem in the case where both forms arise from maximal orders in the same quaternion algebra.

Our work is motivated by several computational questions about supersingular elliptic curves. One problem is, given a maximal order $\mathcal{O}$ in B_p, to compute an elliptic curve E over $\mathbb{F}_{p^2}$ such that $\mathrm{End}(E) \cong \mathcal{O}$. A second problem is to compute a list of all isomorphism classes of supersingular elliptic curves E over $\mathbb{F}_{p^2}$ (or over $\mathbb{F}_p$ in a restricted case) together with a description of $\mathrm{End}(E)$. To solve both problems we use Hilbert class polynomials. The first problem does not seem to have been considered in the literature previously. Cerviño [4] has given an algorithm to solve the second problem that seems to run in $O(p^{3+\varepsilon})$ operations (or $O(p^{2.5+\varepsilon})$ in the restricted case over $\mathbb{F}_p$); our approach leads to a superior running time of $O(p^{2.5+\varepsilon})$ operations (or $O(p^{1.5+\varepsilon})$ in the restricted case). However, the main focus of our paper is the theoretical result, and further details about the algorithms and applications may be developed in future work.

2. BACKGROUND

We recall some basic notions, and introduce some notation that we use in the statement of our main result (Theorem 1).

We let B_p be the quaternion algebra ramified exactly at p and at ∞. A general reference for many of the facts in this section is Vignéras [19]. We recall that B_p is a 4-dimensional division $\mathbb{Q}$-algebra containing $\mathbb{Q}$ and equipped with the symmetric positive definite bilinear form $\mathrm{Tr}(x\overline{y})$ and the associated positive-definite quadratic form $\mathrm{Nr}(x) = \frac{1}{2}\mathrm{Tr}(x\overline{x})$. Every element $x \in B_p$ satisfies its characteristic equation $x^2 - \mathrm{Tr}(x)x + \mathrm{Nr}(x) = 0$. We define B_p^0 the subring of B_p of elements of zero trace.

We let $\mathcal{O}$ and $\mathcal{O}'$ be orders of B_p. We recall that an *order* is a subring of B_p that contains $\mathbb{Z}$ and has 4 linearly independent generators as a $\mathbb{Z}$-module. We recall furthermore that for all $x \in \mathcal{O}$, we have $\mathrm{Tr}(x), \mathrm{Nr}(x) \in \mathbb{Z}$. Finally, we say that $\mathcal{O}$ and $\mathcal{O}'$ are of the same *type* if there exists non-zero $c \in B_p$ such that $c\mathcal{O}c^{-1} = \mathcal{O}'$, and we let the total number of maximal order types be t_p, the *type number* of B_p.

Unless otherwise stated, we will always assume that $\mathcal{O}$ and $\mathcal{O}'$ are maximal, i.e., neither is properly contained in any other order. Deuring showed that, associated to the maximal order $\mathcal{O}$, there exists either one supersingular j-invariant $j(\mathcal{O}) \in \mathbb{F}_p$, or a conjugate pair $j(\mathcal{O}), \overline{j(\mathcal{O})} \in \mathbb{F}_{p^2}$, such that $\mathrm{End}(E(j(\mathcal{O}))) = \mathrm{End}(E(\overline{j(\mathcal{O})})) = \mathcal{O}$, where $E(j)$ is the unique (up to isomorphism) elliptic curve with j-invariant j.

For arbitrary vectors $v_1, v_2, \ldots, v_n$ of a general vector space V we denote by

$$\langle v_1, v_2, \ldots, v_n \rangle := \{a_1 v_1 + a_2 v_2 + \ldots + a_n v_n \mid a_1, a_2, \ldots, a_n \in \mathbb{Z}\}$$

the standard lattice generated by these vectors.

We say that a non-zero lattice element $x \in \Lambda = \langle v_1, v_2, \ldots, v_n \rangle$ is *primitive* if there do not exist $y \in \Lambda$ and $a \in \mathbb{Z}$ such that $ay = x$ and $a \neq \pm 1$. If $x = a_1 v_1 + \ldots + a_n v_n$, then x is primitive if and only if $\gcd(a_1, \ldots, a_n) = 1$. We also say that an integer k is *represented* by $\Lambda = \langle v_1, v_2, \ldots, v_n \rangle$ if there exists $x \in \Lambda$ such that $\mathrm{Nr}(x) = k$, in which case we also say that x *represents* k. Furthermore, we say that x *optimally represents* k if x is primitive.

If $k \neq 0$, we say that k is represented by Λ with *multiplicity* $\theta_\Lambda(k)$, where

$$\theta_\Lambda(k) = \frac{1}{2}\#\{(a_1, \ldots, a_n) \in \mathbb{Z}^n \mid \mathrm{Nr}(a_1 v_1 + \ldots + a_n v_n) = k\},$$

and likewise k is represented optimally by Λ with *optimal multiplicity* $\theta'_\Lambda(k)$, where

$$\theta'_\Lambda(k) = \frac{1}{2}\#\{(a_1, \ldots, a_n) \in \mathbb{Z}^n \mid \mathrm{Nr}(a_1 v_1 + \ldots + a_n v_n) = k, \gcd(a_1, \ldots, a_n) = 1\}.$$

The reason for the factor of $\frac{1}{2}$ is to avoid counting both x and $-x$ with $\mathrm{Nr}(x) = \mathrm{Nr}(-x) = k$, which are effectively the same representations.

For a lattice $\Lambda = \langle v_1, v_2, v_3, v_4 \rangle$ in B_p we define its discriminant as $D(\Lambda) = D(v_1, v_2, v_3, v_4) = |\det(\mathrm{Tr}(v_i v_j))|$ (see Section I.4 of [19]). It is a standard fact that for a maximal order $\mathcal{O} \subset B_p$, it holds that $D(\mathcal{O}) = p^2$ (see, for example, Corollary III.5.3 of Vignéras [19]). Note that the discriminant $D(\mathcal{O})$ of an order $\mathcal{O}$ can also be computed as $|\det(\mathrm{Tr}(v_i \overline{v_j}))|$.

We will often think of B_p simply as an inner product space and forget its algebraic structure. To do this, we can find a $\mathbb{Q}$-basis $\{1, \tau, \rho, \tau\rho\}$ for B_p such that $\tau^2 = -p$, $\rho^2 = -q$ and $\tau\rho = -\rho\tau$, where q is a prime such

that $q \equiv 3 \pmod 8$ and $\left(\frac{-p}{q}\right) = 1$ (see, for example, Lemma 1.1 of Ibukiyama [11]). Then in particular, $\mathrm{Nr}(a + b\tau + c\rho + d\tau\rho) = a^2 + b^2\mathrm{Nr}(\tau) + c^2\mathrm{Nr}(\rho) + d^2\mathrm{Nr}(\tau\rho)$ for $a, b, c, d \in \mathbb{Q}$.

As such, we will embed B_p into $\mathbb{R}^4$ by the mapping

$$\phi : a + b\tau + c\rho + d\tau\rho \mapsto ae_1 + b\sqrt{\mathrm{Nr}(\tau)}e_2 + c\sqrt{\mathrm{Nr}(\rho)}e_3 + d\sqrt{\mathrm{Nr}(\tau\rho)}e_4,$$

where e_i are the usual orthonormal vectors in $\mathbb{R}^4$. We observe that ϕ is indeed an isometry (the quadratic form on $\mathbb{R}^4$ being understood as the square of the standard Euclidean norm). We note that this is not the only standard way to represent B_p (see, for example, Proposition 5.1 of Pizer [14] for a different, but related representation). In particular, the above representation of B_p is not the one used in the two examples of Appendix A.

For a n-dimensional lattice L in $\mathbb{R}^m$, let $\det(L)$, the determinant of L, be the square of the volume of L, i.e., if B is a basis matrix for L then $\det(L) := \det(BB^T) = \mathrm{Vol}(L)^2$. Notice that this is different to the more common definition of $\det(L) = \sqrt{\det(BB^T)} = \mathrm{Vol}(L)$. We will also say that the n successive minima of L are $D_1, D_2, \ldots, D_n \in \mathbb{R}$ such that D_i is minimal such that there exist i linearly independent vectors $v_1, v_2, \ldots, v_i \in L$ with $||v_j||^2 \leq D_i$ for all $j \leq i$. Again we remark that our definition is the square of the more common definition where $||v_j|| \leq D_i$ is taken instead of $||v_j||^2 \leq D_i$.

Likewise, for any lattice $\Lambda \subset B_p$, the determinant, volume and successive minima of Λ are simply those of $\phi(\Lambda)$. We note that for a 4-dimensional lattice $\Lambda \subset B_p$, we have

$$(2.1) \qquad\qquad D(\Lambda) = 16 \det(\phi(\Lambda))$$

since $\mathrm{Tr}(x\overline{y}) = 2\phi(x)\phi(y)^T$.

Under this notation, standard lattice bounds show that there is a minimal constant γ_n (called the n-th Hermite constant) such that

$$(2.2) \qquad\qquad \det(L) \leq \prod_{i=1}^{n} D_i \leq \gamma_n^n \det(L).$$

It is known that $\gamma_2 = \sqrt{4/3}$ (see Section XI.5 of Siegel [16]).

Definition 1. For an order $\mathcal{O} \subset B_p$, we define $\mathcal{O}^T := \{2x - \mathrm{Tr}(x) \mid x \in \mathcal{O}\}$.

We remark that $\mathcal{O}^T$ is a sublattice of $\mathcal{O} \cap B_p^0$, and this inclusion is strict. The set $\mathcal{O}^T$ is called the "Gross lattice" by some authors.

For a negative discriminant $-D$ ($D \equiv 0$ or $3 \pmod 4$), we consider the imaginary quadratic order $\mathcal{O}_{-D} := \mathbb{Z}[\frac{1}{2}(D + \sqrt{-D})]$ of discriminant $-D$. An embedding $i : \mathcal{O}_{-D} \mapsto \mathcal{O}$ is called *optimal* if $(\mathbb{Q} \otimes i(\mathcal{O}_{-D})) \cap \mathcal{O} = i(\mathcal{O}_{-D})$. By a straightforward argument (see, for example, the beginning of Section 3 of Elkies et al. [7]), we see that there is a bijection between primitive elements of $\mathcal{O}^T$ and optimal embeddings in the following sense: for every optimal representation of D in $\mathcal{O}^T$ by a primitive element $x \in \mathcal{O}^T$, there is a unique optimal embedding $i : \mathcal{O}_{-D} \mapsto \mathcal{O}$ such that $i(\sqrt{-D}) = x$, and vice versa. Hence, whenever we talk of an optimal representation or primitive element, we will always associate to it the corresponding optimal embedding.

Throughout the paper we will use the following notation.

Definition 2. Let $\mathcal{O}$ and $\mathcal{O}'$ be two maximal orders in B_p. Let $\mathcal{O}^T$ and $\mathcal{O}'^T$ be as in Definition 1. Let D_1, D_2, D_3 (respectively, D_1', D_2', D_3') be the successive minima of $\mathcal{O}^T$ (respectively, $\mathcal{O}'^T$). Denote by $x, y, z \in \mathcal{O}^T$ elements such that $D_1 = \mathrm{Nr}(x), D_2 = \mathrm{Nr}(y), D_3 = \mathrm{Nr}(z)$. Similarly, denote by $x', y', z' \in \mathcal{O}'^T$ elements such that $D_1' = \mathrm{Nr}(x'), D_2' = \mathrm{Nr}(y'), D_3' = \mathrm{Nr}(z')$.

3. Main Result and Basic Properties

Let notation be as above. We consider the following conditions on D_1, D_2 and p.

$$(3.1) \qquad\qquad D_1 D_2 < \frac{16}{3}p, \ 15 \leq D_1, \ \text{and } 286 < p.$$

Lemma 1 shows that these conditions hold in a significant number of cases.

Lemma 1. *Let $p > 286$ and let $\mathcal{O}$ be a maximal order in B_p such that $j(\mathcal{O}) \in \mathbb{F}_p$. If $15 \leq D_1$ then conditions (3.1) hold.*

Proof. Kaneko [12] proves (see the proof of Theorem 1 on pages 851–852) that if $j(\mathcal{O}) \in \mathbb{F}_p$, then there exists a 2-dimensional sublattice Λ of $\mathcal{O}^T$ with determinant $\det(\Lambda) = 4p$. Let d_1 and d_2 be the two first successive minima of Λ. It is well known that the second Hermite constant is given by $\gamma_2^2 = 4/3$. Using this in (2.2), we obtain that $4p \leq d_1 d_2 < \frac{16}{3}p$. Finally, since $D_i \leq d_i$ for $i = 1, 2$, it follows that $D_1 D_2 \leq \frac{16}{3}p$ as desired. $\qquad\square$

We now state our main result.

Theorem 1. *Let $\mathcal{O}$ and $\mathcal{O}'$ be two maximal orders of B_p and $D_1 = \mathrm{Nr}(x)$, $D_2 = \mathrm{Nr}(y)$, and $D_3 = \mathrm{Nr}(z)$ be the three successive minima of $\mathcal{O}^T$ as in Definition 2. Suppose that D_1, D_2, $\mathrm{Nr}(x+y)$, $\mathrm{Nr}(x-y)$ and D_3 are all represented optimally in $\mathcal{O}'^T$ and that $\theta'_{\mathcal{O}^T}(D_3) \leq \theta'_{\mathcal{O}'^T}(D_3)$. Assume furthermore that (3.1) holds. Then $\mathcal{O}$ and $\mathcal{O}'$ are of the same type.*

We now describe the general strategy of the proof of Theorem 1. Under the conditions (3.1), we show in Lemma 7 that if $\mathcal{O}'^T$ optimally represents D_1 and D_2, then this implies that their first successive minima agree, i.e., $D_1 = D_1'$. Then the fact that $\mathrm{Nr}(x+y)$ and $\mathrm{Nr}(x-y)$ are represented optimally in $\mathcal{O}'^T$ will imply that $D_2 = D_2'$ and $\mathrm{Nr}(x+y) = \mathrm{Nr}(x'+y')$. This is Lemma 8. As a result, by Lemma 9, we can conjugate $\mathcal{O}$ by an appropriate element $c \in B_p$, and assume that $\mathcal{O}^T$ and $\mathcal{O}'^T$ both contain $\langle x, y \rangle$. Finally, since D_3 is also represented by $\mathcal{O}'^T$ outside of $\langle x, y \rangle$, we show that $z = \pm z'$, and so $\mathcal{O}^T$ and $\mathcal{O}'^T$ are isometric. This is done in Lemma 12. We finally conclude by Lemma 5 that $\mathcal{O}$ and $\mathcal{O}'$ are indeed of the same type as desired.

We first develop some basic results that shall be used throughout the proof. As already noted, the discriminant of a maximal order $\mathcal{O} \in B_p$ is p^2. We have the following basic result on the determinant of $\mathcal{O}^T$ which follows directly from standard linear algebra. We state and prove it here for the sake of completeness.

Lemma 2. *Let $\mathcal{O}$ be a maximal order of B_p. Then $\det(\mathcal{O}^T) = 4p^2$.*

Proof. Since $D(\mathcal{O}) = p^2$, equation (2.1) implies $\det(\mathcal{O}) = \frac{p^2}{16}$ and $\mathrm{Vol}(\mathcal{O}) = \sqrt{\det(\mathcal{O})} = \frac{p}{4}$. Let $\mathcal{O} = \langle 1, u_1, u_2, u_3 \rangle$, and consider $\mathcal{O}_1 := \langle 1, 2u_1, 2u_2, 2u_3 \rangle$. Since $\mathrm{Tr}(u_i) \in \mathbb{Z}$, we define $v_i := 2u_i - \mathrm{Tr}(u_i)$ for $1 \leq i \leq 3$ and observe that $\mathcal{O}_1 = \langle 1, v_1, v_2, v_3 \rangle$. We claim that $\mathcal{O}^T = \langle v_1, v_2, v_3 \rangle$. Indeed, we clearly have $\langle v_1, v_2, v_3 \rangle \subseteq \mathcal{O}^T$. Conversely, for any $x \in \mathcal{O}$, we let $x = a + \sum_{i=1}^{3} a_i u_i$ for some $a, a_i \in \mathbb{Z}$, and so

$$2x - \mathrm{Tr}(x) = 2a + 2\sum_{i=1}^{3} a_i u_i - 2a - \sum_{i=1}^{3} a_i \mathrm{Tr}(u_i) = \sum_{i=1}^{3} a_i v_i \in \langle v_1, v_2, v_3 \rangle.$$

Hence $\mathcal{O}^T \subseteq \langle v_1, v_2, v_3 \rangle$, and it follows that $\mathcal{O}^T = \langle v_1, v_2, v_3 \rangle$ as claimed.

To conclude the proof, we observe that $1, u_1, u_2, u_3$ form a $\mathbb{Q}$-basis for B_p, and so $\phi(1), \phi(u_1), \phi(u_2), \phi(u_3)$ form an $\mathbb{R}$-basis for $\mathbb{R}^4$. As a result,
$$\mathrm{Vol}(\mathcal{O}_1) = 8\mathrm{Vol}(\mathcal{O}) = 2p,$$
where the first equality comes from the fact that we have doubled three of the vectors in the basis of $\phi(\mathcal{O})$ to obtain $\phi(\mathcal{O}_1)$. Now since $\phi(1) = e_1$ has length 1 and is orthogonal to $\phi(v_1), \phi(v_2)$ and $\phi(v_3)$, we see that
$$\det(\mathcal{O}^T) = \det(\langle v_1, v_2, v_3 \rangle) = \mathrm{Vol}(\langle \phi(v_1), \phi(v_2), \phi(v_3) \rangle)^2$$
$$= \mathrm{Vol}(\langle e_1, \phi(v_1), \phi(v_2), \phi(v_3) \rangle)^2 = \mathrm{Vol}(\mathcal{O}_1)^2 = 4p^2,$$
as claimed. $\qquad\square$

It is well known (see Section XI.6 of [16]) that the third Hermite constant γ_3 is given by $\gamma_3^3 = 2$. As the determinants of $\mathcal{O}^T$ and $\mathcal{O}'^T$ are $4p^2$, the bounds from (2.2) tell us that

(3.2) $$4p^2 \leq D_1 D_2 D_3, D_1' D_2' D_3' < 8p^2.$$

As a consequence of the upper bound, we observe that $\langle x, y, z \rangle$ cannot be a strict sublattice of $\mathcal{O}^T$. This is because the volume of a lattice Λ always divides the volume of any sublattice $\Lambda' \subseteq \Lambda$, with $\mathrm{Vol}(\Lambda) = \mathrm{Vol}(\Lambda')$ if and only if $\Lambda = \Lambda'$. Hence if $\langle x, y, z \rangle \neq \mathcal{O}^T$, then $\mathrm{Vol}(\langle x, y, z \rangle) \geq 2\mathrm{Vol}(\mathcal{O})$, and so $D_1 D_2 D_3 \geq \det(\langle x, y, z \rangle) \geq 4\det(\mathcal{O}^T) = 16p^2$, which contradicts (3.2). Likewise for $\langle x', y', z' \rangle$, and as a result, we have $\mathcal{O}^T = \langle x, y, z \rangle$ and $\mathcal{O}'^T = \langle x', y', z' \rangle$.

We now observe that since x and y represent the first two successive minima of $\mathcal{O}^T$, we have $\mathrm{Nr}(x+y) = \mathrm{Nr}(x) + \mathrm{Nr}(y) + \mathrm{Tr}(x\overline{y}) \geq \mathrm{Nr}(y)$ and likewise $\mathrm{Nr}(x-y) = \mathrm{Nr}(x) + \mathrm{Nr}(y) - \mathrm{Tr}(x\overline{y}) \geq \mathrm{Nr}(y)$. We hence must have $|\mathrm{Tr}(x\overline{y})| \leq \mathrm{Nr}(x) = D_1$, otherwise one of these two inequalities would not hold. Hence we let

4

$\text{Tr}(x\overline{y}) = \mu D_1$ for some $|\mu| \leq 1$, and WLOG we will take $-1 \leq \mu \leq 0$ (as otherwise we swap the sign of either x or y). Similarly we will let $\text{Tr}(x'\overline{y'}) = \lambda D_1'$ with $-1 \leq \lambda \leq 0$.

Unless otherwise stated, we henceforth always assume

$$(3.3) \qquad\qquad D_2' \leq D_2 \text{ and}$$

$$(3.4) \qquad\qquad 8 \leq D_1 \qquad \text{(which in particular holds true under conditions (3.1)).}$$

Lemma 3. *Let notation be as above. Then* $-1 < \mu, \lambda \leq 0$ *and* $D_1 \neq D_2$.

Proof. We first show that the cases $\mu = -1$ and $\lambda = -1$ are impossible. If $\mu = -1$, then $\text{Nr}(y) = \text{Nr}(x+y)$. Hence D_2 would have two different optimal representations in $\mathcal{O}^T$, and so Theorem 2′ of Kaneko [12] implies that $D_2^2 \geq p^2$. As $D_3 \geq D_2$ and we are assuming (3.4), this would imply that $D_1 D_2 D_3 \geq 8p^2$, which contradicts (3.2), and so $\mu = -1$ is indeed impossible. Similarly if $\lambda = -1$, then $D_2'^2 \geq p^2$. By (3.3) this would imply $D_2 \geq p$, and we again reach the same contradiction. The same application of Kaneko's result tells us that $D_1 \neq D_2$. $\qquad\square$

We derive one final important inequality. We observe that in the proof of Theorem 2′, page 853 of [12], Kaneko proves that p must always divide the quantity $\frac{1}{4}(D_1 D_2 - (2s - D_1 D_2)^2)$, where $s = \text{Tr}(\alpha_1 \alpha_2)$ and where for us, $\alpha_1 = \frac{1}{2}(x + D_1)$ and $\alpha_2 = \frac{1}{2}(y + D_2)$. It is straightforward to verify that

$$s = -\frac{\mu}{4}D_1 + \frac{1}{2}D_1 D_2.$$

Substituting this value for s, we find that $4p$ divides $D_1(D_2 - \frac{\mu^2}{4}D_1)$. The same result applies to $\mathcal{O}'^T$ (which is actually where we will use it), and so defining $M := D_1'(D_2' - \frac{\lambda^2}{4}D_1')$, it follows that

$$(3.5) \qquad\qquad 4p \leq M.$$

We remark that the above with (3.2) gives

$$(3.6) \qquad\qquad 4p \leq D_1 D_2 \quad \text{and} \quad D_3 < 2p,$$

and so in particular under conditions (3.1),

$$(3.7) \qquad\qquad 4p \leq D_1 D_2 \leq \tfrac{16}{3}p \quad \text{and} \quad \tfrac{3}{4}p \leq D_3 < 2p.$$

The following lemma allows us to characterize the conjugacy classes of B_p. For any $x, y \in B_p$, we write $x \sim y$ if there exists non-zero $c \in B_p$ such that $cxc^{-1} = y$.

Lemma 4. *For all* $x, y \in B_p$, *it holds that* $x \sim y$ *if and only if* $\text{Tr}(x) = \text{Tr}(y)$ *and* $\text{Nr}(x) = \text{Nr}(y)$.

Proof. This follows from the Skolem-Noether Theorem, see Theorem I.2.1 of Vignéras [19] or Theorem 5 (on page 10) of Eichler [6] (note that Eichler calls it Wedderburn's Theorem). $\qquad\square$

For an order $\mathcal{O}$, we remark that by writing $\mathcal{O}^T = \langle v_1, v_2, v_3 \rangle$ as in the proof of Lemma 2, it is not difficult to see that $\mathcal{O} = \{x \in 1/2\langle 1, \mathcal{O}^T \rangle : \text{Nr}(x) \in \mathbb{Z}\}$. From this observation we obtain the following lemma which tells us that $\mathcal{O}$ is characterized by $\mathcal{O}^T$.

Lemma 5. *Two orders* $\mathcal{O}, \mathcal{O}' \subset B_p$ *are of the same type if and only if* $\mathcal{O}^T \sim \mathcal{O}'^T$, *i.e., there exists non-zero* $c \in B_p$ *such that* $c\mathcal{O}^T c^{-1} = \mathcal{O}'^T$.

Proof. It is clear that if $c\mathcal{O}c^{-1} = \mathcal{O}'$, then $c\mathcal{O}^T c^{-1} = \mathcal{O}'^T$. Conversely, assume that $c\mathcal{O}^T c^{-1} = \mathcal{O}'^T$. By conjugating $\mathcal{O}$ by c, we see it suffices only to prove that if $\mathcal{O}^T = \mathcal{O}'^T$, then $\mathcal{O}$ and $\mathcal{O}'$ are of the same type. But from the above observation, if $\mathcal{O}^T = \mathcal{O}'^T$, then $\langle 1, \mathcal{O}^T \rangle = \langle 1, \mathcal{O}'^T \rangle$ and so in fact we obtain $\mathcal{O} = \mathcal{O}'$. $\qquad\square$

4. Proof of Theorem 1

We now begin to prove the more technical lemmas which will be used in the proof of Theorem 1. The following lemma will only be used in the context of maximal orders, but we remark that it can be readily generalized to all 2-dimensional lattices.

Lemma 6. *Under the condition $\mu, \lambda \in (-1, 0]$, $x + y$ is the next shortest element of $\langle x, y \rangle$ after $\pm y$ which is not in $\langle x \rangle$, and likewise $x' + y'$ is the next shortest element of $\langle x', y' \rangle$ after $\pm y'$ which is not in $\langle x' \rangle$.*

Proof. We need to check that $\mathrm{Nr}(ax+by) = a^2 D_1 + b^2 D_2 + ab\mu D_1$ will always exceed $\mathrm{Nr}(x+y) = D_1 + D_2 + \mu D_1$ for $a, b \in \mathbb{Z}$ unless $a = b = \pm 1$.

The case $a = 0$ is trivial since $x + y$ is strictly shorter than $2y$. So we assume that $a \geq 1$ (otherwise swap a, b with $-a, -b$ everywhere).

We have $a^2 D_1 + b^2 D_2 + ab\mu D_1 = a D_1(a + b\mu) + b^2 D_2$. So if $a + b\mu \geq 0$ then for $|b| \geq 2$ we have

$$aD_1(a + b\mu) + b^2 D_2 \geq b^2 D_2 = D_2 + D_2(b^2 - 1) > \mathrm{Nr}(x + y).$$

And if $a + b\mu < 0$ then $0 < a < b$ and $-ab < a(a + b\mu)$, and so for $b \geq 2$ we have

$$aD_1(a + b\mu) + b^2 D_2 > bD_2(b - a) \geq 2D_2 \geq \mathrm{Nr}(x + y).$$

Hence we are left with the case $|b| = 1$. We now no longer assume $a \geq 1$, but instead WLOG assume $b = 1$. It is clear that for $|a| \geq 2$ it holds that

$$D_2 + a(a + \mu)D_1 \geq D_2 + 2D_1 > D_2 + D_1 \geq \mathrm{Nr}(x + y).$$

Hence we only have to consider $|a| = 1$ and clearly we have $\mathrm{Nr}(x - y) \geq \mathrm{Nr}(x + y)$ (with equality only if $\mu = 0$), and so indeed $x + y$ is the next shortest element of $\langle x, y \rangle$ after $\pm y$ which not in $\langle x \rangle$ as claimed. The same exact argument applies to $x' + y'$. $\qquad\square$

The following lemma is the first of three technical lemmas, being Lemmas 7, 8 and 12. In these three lemmas we require bounds on D_1, $D_1 D_2$, and sometimes on p. The bounds required by the following Lemma 7 are the strictest and, unlike in Lemmas 8 and 12, we have not yet found a way to loosen them. If the bound on $D_1 D_2$ in the following lemma can be loosened, then the restrictions imposed in Theorem 1 can be loosened as well.

Lemma 7. *Let $\mathcal{O}, \mathcal{O}' \subset B_p$ be two maximal orders as in Definition 2. Assume D_1 and D_2 are both represented optimally by $\mathcal{O}'^T$. Then $D_1 = D_1'$ provided that*

$$(4.1) \qquad\qquad D_1 D_2 < \frac{16}{3}p \ and$$

$$(4.2) \qquad\qquad 8 \leq D_1.$$

Proof. We first prove that the vectors of $\mathcal{O}'^T$ which optimally represent D_1 and D_2 lie in $\langle x', y' \rangle$. Since D_1 and D_2 are represented optimally by $\mathcal{O}'$, we must have $D_1' \leq D_1$ and $D_2' \leq D_2$. Hence by (4.1) we have $D_1' D_2' \leq D_1 D_2 < \frac{16}{3}p$, and so from (3.2) we have

$$\frac{3}{4}p < \frac{4p^2}{D_1' D_2'} \leq D_3'.$$

Since the norm of the shortest element in $\mathcal{O}'^T$ outside $\langle x', y' \rangle$ is D_3', if D_2 is represented outside $\langle x', y' \rangle$ then $\frac{3}{4}p < D_3' \leq D_2$ and hence $D_1 < \frac{16p}{3D_2} < \frac{64}{9} < 8$ which contradicts (4.2). So D_2 cannot be represented outside $\langle x', y' \rangle$. Clearly D_1 cannot be represented outside $\langle x', y' \rangle$ either.

We now assume $D_1 = \mathrm{Nr}(ax' + by')$ with $b \neq 0$. This implies in particular that $D_2' \leq D_1$, and so by (4.1) we have

$$(4.3) \qquad\qquad D_2' < \frac{4}{\sqrt{3}}\sqrt{p}.$$

From Lemma 6, we know that $x' + y'$ is the next shortest element after $\pm y'$ in $\langle x', y' \rangle \setminus \langle x' \rangle$, and we recall from Lemma 3 that $\lambda \in (-1, 0]$ and $D_1 \neq D_2$. The latter implies that D_1 and D_2 must have different

optimal representations in $\mathcal{O}'^T$, and so it follows that $\text{Nr}(x' + y') = D_2' + (1 + \lambda)D_1' \leq D_2$. Combined with $D_2' \leq D_1$, we have that

$$D_2'(D_2' + (1 + \lambda)D_1') \leq D_1 D_2 < \frac{16}{3}p. \tag{4.4}$$

We recall the definition $M = D_1'(D_2' - \frac{\lambda^2}{4}D_1')$, and we will show that $M < 4p$ under the constraints $D_1' \leq \min\{D_2', \frac{1}{1+\lambda}\left(\frac{16p}{3D_2'} - D_2'\right)\}$, where the second term in the min comes from (4.4), and this will be a contradiction to (3.5).

We consider two cases depending on whether or not $D_2' \leq \frac{1}{1+\lambda}\left(\frac{16p}{3D_2'} - D_2'\right)$. Note that this happens when $(D_2')^2(2 + \lambda) \leq 16p/3$.

First note that M is maximised when D_1' is as large as possible. In the case $(D_2')^2(2 + \lambda) \leq 16p/3$ this means $D_1' = D_2'$ and so

$$M \leq D_2'^2\left(\frac{4 - \lambda^2}{4}\right) \leq \frac{16}{3}p\frac{1}{\lambda + 2}\left(\frac{4 - \lambda^2}{4}\right) < 4p.$$

In the case $(D_2')^2(2 + \lambda) > 16p/3$ we take $D_1' = \frac{1}{1+\lambda}\left(\frac{16p}{3D_2'} - D_2'\right)$. Writing $\gamma = (D_2')^2$ we have

$$M \leq \frac{1}{4(1+\lambda)^2\gamma}\left(\frac{16}{3}p - \gamma\right)\left(\gamma(\lambda + 2)^2 - \lambda^2\frac{16}{3}p\right). \tag{4.5}$$

The RHS of (4.5) is subject to the constraints $\gamma = D_2'^2 \leq D_1^2 < \frac{16}{3}p$ (which comes from (4.3)) and $\frac{16}{3(\lambda+2)}p < \gamma$. It is then routine to verify that the RHS of (4.5) is maximized when γ is minimal, i.e., $\gamma = \frac{16}{3(\lambda+2)}p$ (a simple way to verify this is to compute the partial derivative of the RHS of (4.5) with respect to γ and observe that it is negative when $\frac{16|\lambda|p}{3(\lambda+2)} < \gamma$). Substituting $\gamma = \frac{16}{3(\lambda+2)}p$ into the RHS of (4.5) reduces it to $\frac{4}{3}(2 - \lambda)p$, which for $\lambda \in (-1, 0]$ is always less that $4p$.

Hence, in both cases, we obtain that $M < 4p$, which contradicts (3.5). In conclusion, if D_1 and D_2 are both represented optimally by $\mathcal{O}'^T$ with $D_1 = \text{Nr}(ax' + by')$, then we must have $b = 0$ and it follows that $a = 1$ and $D_1 = D_1'$. $\qquad\square$

Lemma 8. *Let $\mathcal{O}, \mathcal{O}' \subset B_p$ be two maximal orders and let notation be as in Definition 2. Assume $D_1 = D_1'$ and that D_2, $\text{Nr}(x + y)$ and $\text{Nr}(x - y)$ are all represented optimally by $\mathcal{O}'^T$. Then $x \sim x'$, $y \sim y'$ and $x + y \sim x' + y'$ (from which it will follow that $\langle x, y\rangle \sim \langle x', y'\rangle$ by Lemma 9) provided that*

$$D_1 D_2 < 7p, \tag{4.6}$$

$$15 \leq D_1, \ and \tag{4.7}$$

$$286 < p. \tag{4.8}$$

Proof. In light of Lemma 4, it suffices to prove that $D_2 = D_2'$ and $\text{Nr}(x + y) = \text{Nr}(x' + y')$ since all vectors in question have zero trace.

Recall that $\text{Nr}(x + y) = (1 + \mu)D_1 + D_2$ and $\text{Nr}(x' + y') = (1 + \lambda)D_1' + D_2'$ where $-1 < \mu, \lambda \leq 0$. To avoid trivial cases later on, we first prove that $\mu, \lambda \neq 0$. From Lemma 6, we know that $\text{Nr}(x + y) \leq \text{Nr}(x - y)$, and if equality held, then $\text{Nr}(x + y) = \text{Nr}(x - y) = D_1 + D_2$, which by Theorem 2' of [12] implies that $(D_1 + D_2)^2 \geq p^2$ and so $D_1 + D_2 \geq p$. As $D_3 \geq D_2$, this in turn implies

$$D_1 D_2 D_3 \geq D_1 D_2^2 \geq D_1(p - D_1)^2 > 8p^2,$$

where the last inequality is true for $15 \leq D_1 < \sqrt{7p}$ and p in (4.8), which contradicts (3.2). As a result $\text{Nr}(x + y) < \text{Nr}(x - y)$ which is indeed equivalent to $\mu \in (-1, 0)$. The same exact argument (keeping in mind that $D_1' = D_1$) shows that $\lambda \neq 0$, and so indeed we have that $\mu, \lambda \in (-1, 0)$.

Now we prove that the vectors in $\mathcal{O}'^T$ which represent $\text{Nr}(x)$, $\text{Nr}(y)$, $\text{Nr}(x + y)$ and $\text{Nr}(x - y)$ all lie in $\langle x', y'\rangle$. The longest of these vectors, $x - y$, has norm $(1 - \mu)D_1 + D_2 \leq 2D_1 + D_2$, which from (4.6) and

(4.7), is bounded by $2D_1 + D_2 < 30 + \frac{7p}{15}$. On the other hand, from $D_2' \leq D_2$ we obtain $D_1' D_2' < 7p$, and hence we have that $\frac{4}{7}p < \frac{4p^2}{D_1' D_2'} \leq D_3'$ from (3.2). This implies that for p in (4.8) we have

$$(4.9) \qquad\qquad 2D_1 + D_2 \leq 30 + \frac{7p}{15} < \frac{4}{7}p < D_3'.$$

Since D_3' is the norm of the shortest element of $\mathcal{O}'^T$ outside $\langle x', y' \rangle$, we see that none of D_1, D_2, $\mathrm{Nr}(x+y)$, $\mathrm{Nr}(x-y)$ can be represented outside $\langle x', y' \rangle$.

Hence assume $D_2 = \mathrm{Nr}(ax' + by')$. Remarking that $a(a + b\lambda) \geq - \left(\frac{\lambda b}{2}\right)^2$, and recalling that $D_1 = D_1'$ by assumption, we obtain

$$D_2 = a^2 D_1' + b^2 D_2' + ab\lambda D_1' = aD_1'(a + b\lambda) + b^2 D_2' \geq b^2 D_2' - \left(\frac{\lambda b}{2}\right)^2 D_1,$$

which implies $D_2' \leq \frac{1}{b^2} D_2 + \frac{\lambda^2}{4} D_1$. Hence by (4.6), for $|b| \geq 2$ we have

$$M = D_1' D_2' - \frac{\lambda^2}{4} D_1'^2 \leq D_1 \left(\frac{1}{b^2} D_2 + \frac{\lambda^2}{4} D_1\right) - \frac{\lambda^2}{4} D_1^2 = \frac{D_1 D_2}{b^2} < 4p,$$

which contradicts (3.5), and so we must have $|b| = 1$. WLOG (changing the sign of a if necessary), we can take $b = 1$.

Now let $\mathrm{Nr}(x+y) = (1 + \mu)D_1 + D_2 = \mathrm{Nr}(cx' + dy') = c^2 D_1' + d^2 D_2' + cd\lambda D_1'$. Remarking as before that $c(c + d\lambda) \geq - \left(\frac{\lambda d}{2}\right)^2$, we obtain

$$\mathrm{Nr}(x + y) = D_1(1 + \mu) + D_2 \geq d^2 D_2' - \left(\frac{\lambda d}{2}\right)^2 D_1'.$$

This with (4.6) implies that, for $|d| \geq 2$, we have

$$M = D_1' D_2' - \frac{\lambda^2}{4} D_1'^2 \leq D_1 \frac{D_1(1 + \mu) + D_2 + \frac{\lambda^2 d^2}{4} D_1}{d^2} - \frac{\lambda^2}{4} D_1^2 \leq \frac{2D_1 D_2}{d^2} < 4p,$$

which again contradicts (3.5), and so we must have $|d| = 1$. WLOG (changing the sign of c if necessary), we can take $d = 1$.

Since $D_1 = D_1'$ and $b = d = 1$, we have

$$(4.10) \qquad\qquad D_2 = a(a + \lambda)D_1 + D_2' \text{ and}$$

$$(4.11) \qquad\qquad D_1(1 + \mu) + D_2 = c(c + \lambda)D_1 + D_2'.$$

We observe that $a \neq c$ since otherwise $\mu = -1$, which is impossible from before. So subtracting (4.10) from (4.11), factorizing and dividing, gives us

$$(4.12) \qquad\qquad \frac{1 + \mu}{c - a} = a + c + \lambda.$$

We observe that if $a = 0$ then $1 + \mu = c(c + \lambda)$, where the LHS is in $(0, 1)$, which implies from the RHS that $c = 1$. But this implies that $D_2 = D_2'$ and $\mathrm{Nr}(x + y) = \mathrm{Nr}(x' + y')$ as desired, and we conclude by Lemma 4.

So we assume now that $a \neq 0$. We note that if $a = 1$, then (4.12) becomes $1 + \mu = c(c + \lambda) - 1 - \lambda$, from which we see that the only possible solution (since the LHS is again in $(0, 1)$) is $c = -1$ and $\lambda = -\frac{1 + \mu}{2} \in (-\frac{1}{2}, 0)$.

We now claim that

$$(4.13) \qquad\qquad D_2 < \frac{7}{4} D_2'.$$

Indeed, if this was not the case, by (4.6) we would have

$$M \leq D_1' D_2' \leq \frac{4}{7} D_1 D_2 < 4p,$$

which contradicts (3.5).

Now (4.13) and (4.10) imply that $a(a + \lambda)D_1 + D_2' = D_2 \leq \frac{7}{4}D_2'$. We remark that $a(a + \lambda) > 0$ for all integers $a \neq 0$. Hence we have

$$(4.14) \qquad D_1 \leq \frac{3D_2'}{4a(a + \lambda)}.$$

Now let $\text{Nr}(x - y) = (1 - \mu)D_1 + D_2 = \text{Nr}(ex' + fy') = e^2 D_1' + f^2 D_2' + ef\lambda D_1'$. We remark that $e^2 + \lambda ef \geq -\left(\frac{\lambda f}{2}\right)^2$, and so with (4.14), we have

$$D_2 \geq f^2 D_2' + \left(-\left(\frac{\lambda f}{2}\right)^2 - (1 - \mu)\right)D_1 \geq D_2'\left(f^2 - \frac{3}{4a(a + \lambda)}\left(1 - \mu + \frac{\lambda^2 f^2}{4}\right)\right)$$

$$(4.15) \qquad = D_2'\left(f^2\left(1 - \frac{3\lambda^2}{16a(a + \lambda)}\right) - \frac{3(1 - \mu)}{4a(a + \lambda)}\right).$$

We observe that for all $\lambda \in (-1, 0)$ and $a \in \mathbb{Z}$, with $a \neq 0$, and with $\lambda \in (-1/2, 0)$ when $a = 1$, it holds that

$$\delta = 1 - \frac{3\lambda^2}{16a(a + \lambda)} > 0.$$

Hence for all $|f| \geq 2$, it holds that

$$(4.16) \qquad D_2 \geq D_2'\left(4\delta - \frac{3(1 - \mu)}{4a(a + \lambda)}\right) \geq D_2'\left(4 - \frac{3(1 - \mu + \lambda^2)}{4a(a + \lambda)}\right).$$

By separating into the cases $a \leq -2, a = -1, a = 1$ and $a \geq 2$, it can be readily checked that for $\lambda, \mu \in (-1, 0)$ and $a \in \mathbb{Z}$, with $a \neq 0$, and with $\lambda = -\frac{1+\mu}{2}$ when $a = 1$, it holds that

$$\frac{1 - \mu + \lambda^2}{a(a + \lambda)} \leq \frac{5}{2},$$

with equality only in the case that $a = 1$ and $\mu = 0$, $\lambda = -\frac{1}{2}$. As a result,

$$D_2 \geq D_2'\left(4 - \frac{15}{8}\right) > \frac{7}{4}D_2',$$

which contradicts (4.13). We conclude that $|f| \geq 2$ is impossible, and hence WLOG, we take $f = 1$.

We now have

$$(4.17) \qquad D_1(1 - \mu) + D_2 = eD_1(e + \lambda) + D_2'.$$

Viewing (4.10) and (4.17), we observe that $e \neq a$, as otherwise we would have $\mu = 1$, which is impossible. Hence subtracting (4.10) from (4.17) we obtain

$$(4.18) \qquad \frac{1 - \mu}{e - a} = a + e + \lambda.$$

Viewing this in conjunction with (4.12), we wish to find the possible solutions to (4.12) and (4.18) with $a, c, e \in \mathbb{Z}$, $a \neq 0$, and $\lambda, \mu \in (-1, 0)$.

We observe that if $e - a = 1$ then the LHS of (4.18) is in $(1, 2)$, which implies $a + e = 2$. However this implies $2e = 3$, which is impossible. If $e - a = -1$, then the LHS of (4.18) is in $(-2, -1)$, which implies $a + e = -1$. However this implies $e = -1$ and $a = 0$, and we already saw that $a = 0$ implied the result of the theorem.

So we are only left to consider the case that $|e - a| \geq 2$. If $e - a \geq 2$, then the LHS of (4.18) is in $(0, 1)$, which implies that $a + e = 1$. If $e - a \leq -2$ then the LHS of (4.18) is in $(-1, 0)$, which implies that $a + e = 0$. Exactly the same reasoning applies to (4.12) with e replaced by c. As a result, we have the following implications:

$$c - a \geq 2 \Longrightarrow a + c = 1 \Longrightarrow 1 - 2a \geq 2 \Longrightarrow a < 0,$$
$$c - a \leq -2 \Longrightarrow a + c = 0 \Longrightarrow -2a \leq -2 \Longrightarrow a > 0,$$
$$e - a \geq 2 \Longrightarrow a + e = 1 \Longrightarrow 1 - 2a \geq 2 \Longrightarrow a < 0,$$
$$e - a \leq -2 \Longrightarrow a + e = 0 \Longrightarrow -2a \leq -2 \Longrightarrow a > 0,$$

with other values for $c - a$ and $e - a$ being impossible.

From this we see that if $a > 0$, then the only possibility for e and c is $e = c = -a$, and if $a < 0$, then the only possibility is $e = c = 1 - a$. In either case we obtain $e = c$. But together with (4.12) and (4.18), this implies that $1 + \mu = 1 - \mu$ and so $\mu = 0$, which we excluded earlier.

We conclude that the only possible solution to $D_2 = \mathrm{Nr}(ax' + by')$, $\mathrm{Nr}(x + y) = \mathrm{Nr}(cx' + dy')$ and $\mathrm{Nr}(x - y) = \mathrm{Nr}(ex' + fy')$ is $a = 0$, $b = 1$, $c = 1$, $d = 1$, $e = -1$, $f = 1$ (and the corresponding negative solutions if we wish to change signs). This implies by Lemma 4 that $y \sim y'$ and $x + y \sim x' + y'$ as desired. $\quad\square$

Remark 1. The bottleneck in the proof was in (4.9), which we used to show that $\mathrm{Nr}(x - y)$ could not be represented outside $\langle x', y' \rangle$. In this inequality, we see that the bound (4.6) could be replaced by $D_1 D_2 < mp$, where m is such that $m < \sqrt{60}$. An appropriate change to (4.8) would then also need to be made. It can easily be verified that all other inequalities in the proof will hold for all such m, so indeed (4.9) is the limiting factor in the proof. Since $D_1 D_2 < \frac{16}{3}p$ is already the limiting factor in Lemma 7, we used the bound $7p$ in Lemma 8 for sake of simplicity.

Remark 2. Departing from the assumption $D_1 = D_1'$, it becomes easier to show our desired result, in the sense that the bound $D_1 D_2 < \frac{16}{3}p$ from Lemma 7 can be loosened to $D_1 D_2 < mp$ for m as in Remark 1. This seems a little strange, as intuitively, $D_1 = D_1'$ should be the most obvious condition which should be satisfied. Furthermore, the proof of Lemma 7 did not use the assumption that $\mathrm{Nr}(x + y)$ and $\mathrm{Nr}(x - y)$ are also optimally represented by $\mathcal{O}'^T$. This suggests that there could be an alternative way to prove that $D_1 = D_1'$ than in Lemma 7, and hence to loosen the conditions imposed by Theorem 1.

Lemma 9. *Let $\mathcal{O}, \mathcal{O}' \subset B_p$ be two maximal orders and let notation be as in Definition 2. Assume that $x \sim x'$, $y \sim y'$ and $x + y \sim x' + y'$. It follows then that $\langle x, y \rangle \sim \langle x', y' \rangle$, i.e., there exists non-zero $c \in B_p$ such that $c\langle x, y \rangle c^{-1} = \langle x', y' \rangle$.*

Proof. As $\mathrm{Tr}(\mathcal{O}^T) = \mathrm{Tr}(\mathcal{O}'^T) = 0$, for all $r \in \mathcal{O}^T$ and $r' \in \mathcal{O}'^T$, it holds that $r \sim r'$ if and only if $\mathrm{Nr}(r) = \mathrm{Nr}(r')$ by Lemma 4. It follows that

$$\mathrm{Nr}(x') + \mathrm{Nr}(y') + \mathrm{Tr}(x'\overline{y'}) = \mathrm{Nr}(x' + y') = \mathrm{Nr}(x + y) = \mathrm{Nr}(x) + \mathrm{Nr}(y) + \mathrm{Tr}(x\overline{y}),$$

and we obtain $\mathrm{Tr}(x\overline{y}) = \mathrm{Tr}(x'\overline{y'})$.

We recall that for any $u, v \in B_p$, we have

$$uv + vu = \mathrm{Tr}(u)v + \mathrm{Tr}(v)u + \mathrm{Tr}(uv) - \mathrm{Tr}(u)\mathrm{Tr}(v).$$

From this, it follows that $\langle 1, x, y, xy \rangle$ and $\langle 1, x', y', x'y' \rangle$ are both rings (we simply need to check that the product of any two generators stays within the lattice), and hence they are both orders. Furthermore, since $\overline{x} = -x$, $\overline{y} = -y$ and $\mathrm{Tr}(x\overline{y}) = \mathrm{Tr}(x'\overline{y'})$, we obtain that these orders are isomorphic under the natural mapping $\psi : a + bx + cy + dxy \mapsto a + bx' + cy' + dx'y'$. Since all isomorphisms of orders come from conjugation, we know that there exists non-zero $c \in B_p$ such that $c\langle 1, x, y, xy \rangle c^{-1} = \langle 1, x', y', x'y' \rangle$, and in particular, the conclusion of the lemma follows. $\quad\square$

The previous lemma simplifies the situation, in that we can conjugate $\mathcal{O}$ by an appropriate element $c \in B_p$ and hence assume that $x = x'$ and $y = y'$. It remains to deal with D_3.

Lemma 10. *Let $\mathcal{O}, \mathcal{O}' \subset B_p$ be two maximal orders and let notation be as in Definition 2. Suppose that $x = x'$ and $y = y'$. Suppose furthermore that there exists $w \in \mathcal{O}'^T$, $w \notin \langle x, y \rangle$, such that $\mathrm{Nr}(w) = D_3$. It holds then that $\mathcal{O}'^T = \langle x, y, w \rangle$, i.e., $\{x, y, w\}$ forms a $\mathbb{Z}$-basis for $\mathcal{O}'^T$.*

Lemma 10 is true for any two 3-dimensional lattices of equal determinant defined over a space with a positive bilinear form, but we will only use it in the context given above.

Proof of Lemma 10. Consider the 2-dimensional subspace

(4.19) $$\langle x, y \rangle^\perp := \{v \in B_p \mid \mathrm{Tr}(v\overline{x}) = \mathrm{Tr}(v\overline{y}) = 0\}.$$

As x, y have zero trace, we see that $\mathbb{Q} \subset \langle x, y \rangle^\perp$, and so we can suppose $\langle x, y \rangle^\perp$ has $\mathbb{Q}$-basis $\{1, v\}$ with $\mathrm{Tr}(v) = 0$. Let $u \in \langle x, y \rangle^\perp$ be the projection of z onto $\langle x, y \rangle^\perp$ (that is, $u = \frac{\mathrm{Tr}(z\overline{v})}{2\mathrm{Nr}(v)}v$). Let $D_3' = \mathrm{Nr}(z')$ be

10

the third successive minima of $\mathcal{O}'^T$ as usual. Let $u' \in \langle x, y \rangle^\perp$ be projection of z' onto $\langle x, y \rangle^\perp$. Then we have (recalling that the determinant is the square of the volume of a lattice)

$$(4.20) \qquad \det(\langle x, y \rangle)\mathrm{Nr}(u) = \det(\mathcal{O}^T) = \det(\mathcal{O}'^T) = \det(\langle x, y \rangle)\mathrm{Nr}(u').$$

Since $u, u' \in \langle v \rangle$, we note that this implies $u = \pm u'$. Now we observe that

$$\det(\mathcal{O}^T) \le \det(\langle x, y \rangle)\mathrm{Nr}(z) \le D_1 D_2 D_3 < 2\det(\mathcal{O}^T),$$

from which it follows that

$$(4.21) \qquad \mathrm{Nr}(z) = D_3 < \frac{2\det(\mathcal{O}^T)}{\det(\langle x, y \rangle)}.$$

On the other hand, as D_3 is represented by $w \in \mathcal{O}'^T = \langle x, y, z' \rangle$ outside of $\langle x, y \rangle$, we have that $w = ax + by + cz'$ for some $a, b, c \in \mathbb{Z}$, $c \neq 0$. Therefore

$$D_3 = \mathrm{Nr}(w) = \mathrm{Nr}(ax + by + cz') \ge c^2 \mathrm{Nr}(u') = c^2 \frac{\det(\mathcal{O}^T)}{\det(\langle x, y \rangle)},$$

where the last equality comes from (4.20). Combined with (4.21), this implies that $c = \pm 1$, and the conclusion follows. $\qquad\square$

The following lemma will be used in Lemma 12.

Lemma 11. *Let $u, v \in \mathcal{O}^T$. It then holds that $uv - \frac{1}{2}\mathrm{Tr}(uv) \in \mathcal{O}^T \cap \langle u, v \rangle^\perp$, where $\langle u, v \rangle^\perp$ is defined in (4.19).*

Proof. We observe that $\mathrm{Tr}(uv\overline{u}) = \mathrm{Tr}(uv\overline{v}) = 0$ since both u and v have zero trace. So we have $uv \in \langle u, v \rangle^\perp$, and since $\mathbb{Q} \subset \langle u, v \rangle^\perp$, it follows that indeed $uv - \frac{1}{2}\mathrm{Tr}(uv) \in \langle u, v \rangle^\perp$.

Now let $u = 2a - \mathrm{Tr}(a), v = 2b - \mathrm{Tr}(b) \in \mathcal{O}^T$ for some $a, b \in \mathcal{O}$, and define $t := 2ab - \mathrm{Tr}(a)b - \mathrm{Tr}(b)a \in \mathcal{O}$. It is easy to verify that

$$uv - 2t = \mathrm{Tr}(a)\mathrm{Tr}(b) \in \mathbb{Q}.$$

It follows that $uv - \frac{1}{2}\mathrm{Tr}(uv) = 2t - \mathrm{Tr}(t)$. Since $2t - \mathrm{Tr}(t) \in \mathcal{O}^T$, this implies that $uv - \mathrm{Tr}(uv) \in \mathcal{O}^T$ as desired. $\qquad\square$

Lemma 12. *Let $\mathcal{O}, \mathcal{O}' \subset B_p$ be two maximal orders and let notation be as in Definition 2. Suppose that $x = x'$ and $y = y'$. Suppose furthermore that there exists $w \in \mathcal{O}'^T$, $w \notin \langle x, y \rangle$, such that $\mathrm{Nr}(w) = D_3$. It then holds that $z = \pm z'$ (from which it follows that $\mathcal{O}^T = \mathcal{O}'^T$) provided that*

$$(4.22) \qquad D_1 D_2 < \frac{16}{3}p,$$

$$(4.23) \qquad 15 \le D_1, \ and$$

$$(4.24) \qquad 168 < p.$$

Proof. As in the proof of Lemma 10, we let u and u' be the projections of z and z' onto $\langle x, y \rangle^\perp$. Hence, $z = (\alpha x + \beta y) + u$ for some $\alpha, \beta \in \mathbb{Q}$, and since $x, y, z \in \mathcal{O}^T$, it follows that $\overline{u} = -u$ and so $u \in \mathcal{O}^T$, and similarly for z'. We are in the same situation as Lemma 10, and in particular (4.20) holds, which implies $u = \pm u'$. By changing sign of z' if necessary, we can WLOG assume $u = u'$. Furthermore, we know by Lemma 10 that $\mathcal{O}'^T = \langle x, y, w \rangle$, and so WLOG the projection of w onto $\langle x, y \rangle^\perp$ is also u.

We let $s := xy - \frac{1}{2}\mathrm{Tr}(xy)$, which by Lemma 11, lies in $\mathcal{O}^T \cap \langle x, y \rangle^\perp$ and in $\mathcal{O}'^T \cap \langle x, y \rangle^\perp$. We hence let $s = ax + by + cz$ and $s = a'x + b'y + c'w$ for some $a, b, c, a', b', c' \in \mathbb{Z}$.

Since $s \in \langle x, y \rangle^\perp$, and u is the projection of z and w onto $\langle x, y \rangle^\perp$, it holds that $s = cu = c'u$, which implies $c = c'$. Furthermore, we have that

$$(4.25) \qquad \mathrm{Nr}(ax + by) = \mathrm{Nr}(s - cz) = \mathrm{Nr}(s) + c^2\mathrm{Nr}(z) - c\mathrm{Tr}(s\overline{z}) \text{ and}$$

$$(4.26) \qquad \mathrm{Nr}(a'x + b'y) = \mathrm{Nr}(s - cw) = \mathrm{Nr}(s) + c^2\mathrm{Nr}(w) - c\mathrm{Tr}(s\overline{w}).$$

11

The fact that the projections of z and w onto $\langle x, y \rangle^{\perp}$ are equal, implies that $\mathrm{Tr}(s\overline{z}) = \mathrm{Tr}(s\overline{w})$. We also recall that $\mathrm{Nr}(z) = D_3 = \mathrm{Nr}(w)$. Together with (4.25) and (4.26), this implies that

$$(4.27) \qquad \mathrm{Nr}(ax + by) = \mathrm{Nr}(a'x + b'y).$$

We will now show that $\mathrm{Nr}(ax + by)$ cannot be too large and then apply Theorem 2' of [12] to conclude that $ax + by = \pm(a'x + b'y)$. Recall that $u = -\alpha x - \beta y + z$, for some $\alpha, \beta \in \mathbb{Q}$. We claim that the closest element to $\alpha x + \beta y$ in the lattice $\langle x, y \rangle$ is 0. Indeed, suppose a non-zero element $k \in \langle x, y \rangle$ was closer to $\alpha x + \beta y$ than 0 and consider the element $z + k$. Then $\mathrm{Nr}(-z - k) = \mathrm{Nr}(u) + \mathrm{Nr}(\alpha x + \beta y - k)$. However we then obtain $\mathrm{Nr}(\alpha x + \beta y - k) < \mathrm{Nr}(\alpha x + \beta y)$, since $\alpha x + \beta y$ is closer to k than to 0. But this implies $\mathrm{Nr}(-z - k) < \mathrm{Nr}(z)$, and since $-z - k$ is outside of $\langle x, y \rangle$, this contradicts the fact that z represents the third successive minima of $\mathcal{O}^T$. Hence, 0 is the closest element of $\langle x, y \rangle$ to $\alpha x + \beta y$ as claimed. It is well known that the covering radius $\rho(\Lambda)$ of a lattice Λ is always bounded by $\rho(\Lambda) \leq \sigma(\Lambda)/2$, where $\sigma(\Lambda)$ is the length of the diagonal of the orthogonal parallelepiped of Λ (see, for example, Theorem 7.9, page 138 of Micciancio and Goldwasser [9]). As a result, we have that

$$\mathrm{Nr}(\alpha x + \beta y) \leq \rho(\langle x, y \rangle)^2 \leq \frac{1}{4}\sigma(\langle x, y \rangle)^2 \leq \frac{1}{4}(D_1 + D_2).$$

Since $s = cu$, it holds that $a = c\alpha$ and $b = c\beta$, and so

$$(4.28) \qquad \mathrm{Nr}(ax + by) = c^2\mathrm{Nr}(\alpha x + \beta y) \leq \frac{c^2}{4}(D_1 + D_2).$$

We now bound c. By (3.2), we have that

$$\frac{1}{2}D_1 D_2 D_3 < 4p^2 = \det(\langle x, y, z \rangle) \leq D_1 D_2 \mathrm{Nr}(u).$$

It follows that $D_3 < 2\mathrm{Nr}(u)$. Furthermore, we observe that

$$c^2 \mathrm{Nr}(u) = \mathrm{Nr}(s) = \mathrm{Nr}(xy - \tfrac{1}{2}\mathrm{Tr}(xy)) \leq \mathrm{Nr}(xy) = D_1 D_2.$$

Hence

$$(4.29) \qquad D_3 < \frac{2}{c^2}D_1 D_2.$$

On the other hand, by (4.22) and (3.2), we obtain

$$(4.30) \qquad \frac{9}{64}D_1 D_2 < \frac{3}{4}p < \frac{4p^2}{D_1 D_2} \leq D_3.$$

Combined with (4.29), this gives us $c^2 < \frac{128}{9} < 15$. As $c \in \mathbb{Z}$, this implies that $c^2 \leq 9$. Therefore, from (4.28), we obtain

$$(4.31) \qquad \mathrm{Nr}(ax + by) \leq \frac{9}{4}(D_1 + D_2) < \frac{9}{4}(15 + \frac{\frac{16}{3}p}{15}) < p,$$

where the last two inequalities follow from (4.22), (4.23) and (4.24). However, since $\mathrm{Nr}(a'x + b'y) = \mathrm{Nr}(ax + by)$ from (4.27), we obtain by Theorem 2' of [12] that $ax + by = \pm(a'x + b'y)$, and so $z = \pm z'$ as desired. $\square$

Remark 3. As in the discussion of Lemma 8 in Remark 1, we can loosen the bound (4.22) to $D_1 D_2 < mp$, where m is such that $m < \sqrt{32}$. This maintains the fact that (4.29) and (4.30) imply the inequality $c^2 < 16$. It can be readily checked that for all $m < \sqrt{32}$, all other inequalities in the proof hold for sufficiently large p. We could even increase m above $\sqrt{32}$, thus losing the implication that $c^2 < 16$, but changing (4.23) to $M(m) \leq D_1$, for $M(m)$ sufficiently large and dependent on m. The important fact to check would be that the corresponding version of (4.31) is still bounded above by p for our choice of m. However, since $D_1 D_2 < \frac{16}{3}p$ and $15 \leq D_1$ are already the limiting factors in Lemma 7, for simplicity we have chosen to take $m = \frac{16}{3}$ here too.

Proof of Theorem 1. Assume that D_1, D_2, $\mathrm{Nr}(x + y)$, $\mathrm{Nr}(x - y)$ and D_3 are all optimally represented in $\mathcal{O}'^T$ and that $\theta'_{\mathcal{O}^T}(D_3) \leq \theta'_{\mathcal{O}'^T}(D_3)$. From Lemma 6, we know that $D_1' = D_1$. Hence, from Lemma 8, we have that $y \sim y'$ and $x + y \sim x' + y'$. By consequence, from Lemma 9, by conjugating $\mathcal{O}'$ by an appropriate element $c \in B_p$, we can assume that $\langle x, y \rangle = \langle x', y' \rangle$. Now, in order that $\theta'_{\mathcal{O}^T}(D_3) \leq \theta'_{\mathcal{O}'^T}(D_3)$, we require

that D_3 is represented in $\mathcal{O}'^T$ outside of $\langle x, y \rangle$. Hence, by Lemma 12, we must have $\mathcal{O}^T = \mathcal{O}'^T$. By Lemma 5, this implies that $\mathcal{O}$ and $\mathcal{O}'$ are of the same type as desired. This completes the proof of Theorem 1. $\qquad \square$

5. Algorithm to Associate Elliptic Curves to Maximal Orders

In this section we consider the following problem: Given a maximal order $\mathcal{O} \subset B_p$, to compute an elliptic curve $E/\mathbb{F}_{p^2}$ such that $\operatorname{End}(E) \cong \mathcal{O}$. Our approach is to determine $j(E)$ using Hilbert class polynomials. We give a general method, but we are only able to prove that this method terminates when conditions (3.1) hold (e.g., when $\sqrt{-p} \in \mathcal{O}$ and so $j(E) \in \mathbb{F}_p$).

Let $H_{-D}(X) \in \mathbb{F}_p[X]$ be the Hilbert class polynomial of discriminant $-D$ reduced modulo p (see Section 13 of Cox [5]). We recall that $H_{-D}(X) \in \mathbb{Z}[X]$ is the polynomial whose roots are the j-invariants of the elliptic curves over $\mathbb{C}$ possessing the quadratic order $\mathcal{O}_{-D} = \mathbb{Z}[\frac{1}{2}(D + \sqrt{-D})]$ as their endomorphism ring.

Note that if $\sqrt{-p} \in \mathcal{O}$ then $\mathcal{O}$ can be written in a canonical form given by Ibukiyama [11]. For example, when $p \equiv 1 \pmod 4$ then there exists a prime q and an integer r such that $q \mid (r^2 + p)$ and such that $\mathcal{O}$ is isomorphic to an order with $\mathbb{Z}$-basis $\{1, (1+j)/2, i(1+j)/2, (r+i)j/q\}$ in the quaternion algebra defined by $i^2 = -p, j^2 = -q$ and $ij = -ji$. In the case $p \equiv 3 \pmod 4$ there are two such families of orders. Note that $j(E) \in \mathbb{F}_p$ is a root of $H_{-p}(X)$ and either $H_{-q}(X)$ or $H_{-4q}(X)$. When q is small this already gives an efficient way to determine $j(E)$, however we cannot assume that q is always small in Ibukiyama's result.

The idea of the algorithm is to find several small norms $d_1, d_2, \ldots, d_n$ of primitive elements in $\mathcal{O}^T$, and to note that $(X - j(E))$ is a factor of $\gcd(H_{-d_1}(X), H_{-d_2}(X), \ldots, H_{-d_n}(X))$. Theorem 1 shows that if (3.1) holds, then the algorithm is guaranteed to terminate within a bounded time. The condition (3.1) holds in particular when $j(\mathcal{O}) \in \mathbb{F}_p$. Some examples of the use of the method are given in Appendix A.

The above sketch is made precise in Theorem 2 and Algorithm 1. We first remark that if $\mathcal{O}$ has a unit (element of norm 1) other than ± 1, then it is known that $j(\mathcal{O}) \in \{0, 1728\}$. Precisely, $j(\mathcal{O}) = 0$ if there is a unit of (multiplicative) order 3 or 6, and $j(\mathcal{O}) = 1728$ if there is a unit of order 4. So these cases pose no problems in identifying $j(\mathcal{O})$. In the following theorem, the cases $d = 3$ and $d = 4$ would have corresponded to non-trivial units of $\mathcal{O}$ when $j(\mathcal{O}) = 1728$ and $j(\mathcal{O}) = 0$ respectively.

Theorem 2. *Assume that $\mathcal{O}$ has no units other than ± 1. Then $d > 4$ is represented optimally by $\mathcal{O}^T$ with optimal multiplicity m if and only if $j(\mathcal{O})$ appears as a root of $H_{-d}(X) \in \mathbb{F}_p[X]$ with multiplicity εm, where $\varepsilon = 1$ or 2 according to whether p is inert or ramified in $\mathbb{Q}(\sqrt{-d})$, i.e., p does not divide or does divide the discriminant $\Delta_{\mathbb{Q}(\sqrt{-d})}$ respectively.*

Proof. This can be viewed as a special case of Lemma 3.2 of Elkies et al. [7], where the maximal order has no non-trivial units, and so the equivalence class of any optimal embedding i is simply i itself. We may assume p is inert or ramified because if p splits then the roots of $H_{-d}(X)$ correspond to ordinary elliptic curves. $\square$

We will use Theorem 2 to distinguish orders that have different optimal multiplicities for some integer d_n. We use derivatives to achieve this; recall that if a polynomial $p(X)$ over a field $\mathbb{F}$ has $x_0 \in \mathbb{F}$ as a root with multiplicity $m \geq 1$, then it holds that $p'(X)$ has x_0 as a root with multiplicity $m - 1$.

Algorithm 1

Input: A $\mathbb{Z}$-basis of a maximal order $\mathcal{O} \subset B_p$.

Output: The minimal polynomial of the j-invariant(s) $j(\mathcal{O}) \in \mathbb{F}_{p^2}$ such that $\operatorname{End}(E(j(\mathcal{O}))) = \mathcal{O}$.

Procedure:
 (1) If $\mathcal{O}$ has a unit other than ± 1, output the polynomial corresponding to $j(\mathcal{O}) = 0$ or $j(\mathcal{O}) = 1728$ accordingly (see discussion before Theorem 2) and terminate. Otherwise construct a $\mathbb{Z}$-basis of the sublattice $\mathcal{O}^T$, and set $n = 1$, $k = 0$, $\mathbf{C} = 0$ and $G(X) = 0$.
 (2) Find $y_n \in \mathcal{O}^T$ such that y_n is primitive (so $y_n \neq 0$) and $y_n \neq \pm y_i$ for all $1 \leq i < n$, and such that $\operatorname{Nr}(y_n)$ is minimal over all such possible y_n.
 (3) Set $d_n = \operatorname{Nr}(y_n)$. If p divides $\Delta_{\mathbb{Q}(\sqrt{-d_n})}$, set $\varepsilon = 2$, otherwise set $\varepsilon = 1$. If $d_n = d_{n-1}$ set $k = k + \varepsilon$, otherwise set $k = \varepsilon - 1$. If $\varepsilon = 2$ and $k = 1$, set $G(X) = \gcd(G(X), H_{-d_n}(X), H'_{-d_n}(X)) \in \mathbb{F}_p[X]$.

13

Otherwise set $G(X) = \gcd(G(X), H_{-d_n}^{(k)}(X)) \in \mathbb{F}_p[X]$, where $H_{-d_n}^{(k)}(X)$ is the k-th derivative of $H_{-d_n}(X)$, and $H_{-d_n}^{(0)}(X) = H_{-d_n}(X)$.

(4) If $G(X)$ is either linear, or quadratic and irreducible over $\mathbb{F}_p$, output $G(X)$ and terminate. If $\mathbf{C} = 1$, or if $n = 2$, $15 \leq d_1$ and $d_1 d_2 < \frac{16}{3}p$, proceed to Step 5. Otherwise set $n = n + 1$ and return to Step 2.

(5) If $n = 2$, set $\mathbf{C} = 1$, $n = 3$ and $y_3 = y_1 \pm y_2$, where $+/-$ is chosen to minimize $\mathrm{Nr}(y_3)$. If $n = 3$, set $n = 4$ and $y_4 = y_1 \pm y_2$, such that $y_4 \neq y_3$. If $n = 4$, set $n = 5$ and find y_5 outside the sublattice $\langle y_1, y_2 \rangle$ such that $\mathrm{Nr}(y_5)$ is minimal. Return to Step 3.

If the conditions (3.1) hold (e.g., if $j(\mathcal{O}) \in \mathbb{F}_p$) then the algorithm terminates. Furthermore, in this case we only need to consider $n \leq 5$ (this is the reason for the addition of Step 5, which otherwise seems completely unmotivated).

We hope that the algorithm terminates in all cases, but we do not have a proof of this (see discussion in the following paragraph). We note that since d_1 in Step 2 is simply the first successive minima of $\mathcal{O}^T$, it must satisfy $d_1 < p$ (otherwise we contradict (3.2)). Hence by Theorem 2′ of Kaneko [12] (namely, that if there are two different embeddings of $\mathbb{Z}[(d + \sqrt{d})/2]$ into $\mathcal{O}$ then $d^2 \geq p^2$) and Theorem 2 above, $H_{-d_1}(X)$ is square-free, and hence so is $G(X)$ after the first iteration of Step 3. Along with Theorem 2, this implies that if it terminates, Algorithm 1 does compute the correct minimal polynomial of $j(\mathcal{O})$. The reason for taking the derivative in Step 3 is to take into account the case of multiple roots of $H_{-d_n}(X)$, i.e., when $\theta_{\mathcal{O}^T}(d_n) \geq 2$, or when p divides $\Delta_{\mathbb{Q}(\sqrt{-d_n})}$.

Let us temporarily stop the algorithm for some $n > 0$ just after Step 3, and for simplicity, let us assume that $d_{n-1} \neq d_n$. Consider the polynomial $G(X)$. One of its roots (or two in the case of a conjugate pair) will be the desired j-invariant $j(\mathcal{O})$. If $j(\mathcal{O}')$ is another root of $G(X)$, what can we say about the associated maximal order $\mathcal{O}'$? It must be the case that $\theta_{\mathcal{O}^T}(k) \leq \theta_{\mathcal{O}'^T}(k)$ for all integers $k \leq d_{n-1}$, in which case we say that $\mathcal{O}'^T$ *optimally dominates* $\mathcal{O}^T$ *up to* d_{n-1}. If the algorithm never terminates, it is clear then that there must exist a maximal order $\mathcal{O}'$ such that $\theta_{\mathcal{O}^T}(k) \leq \theta_{\mathcal{O}'^T}(k)$ for all $k > 0$, i.e., $\mathcal{O}'^T$ optimally dominates $\mathcal{O}^T$ up to b for all $b > 0$, in which case we simply say that $\mathcal{O}'^T$ *optimally dominates* $\mathcal{O}^T$. So the question of whether Algorithm 1 terminates, and if so, under what running time, is equivalent to the question of whether there exists another maximal order $\mathcal{O}' \subset B_p$, of a different type to $\mathcal{O}$, such that $\mathcal{O}'^T$ optimally dominates $\mathcal{O}^T$, and if not, what is a bound $b > 0$ such that $\mathcal{O}'^T$ does not optimally dominate $\mathcal{O}^T$ up to b for all other maximal orders $\mathcal{O}' \subset B_p$. We suspect that such an order $\mathcal{O}'$ does not exist and we propose the following two conjectures.

Conjecture 1. There do not exist two maximal orders $\mathcal{O}, \mathcal{O}' \subset B_p$ of different types such that $\mathcal{O}'^T$ optimally dominates $\mathcal{O}^T$.

Conjecture 2. There exists a bound $b = O(p)$ such that for all maximal orders $\mathcal{O}, \mathcal{O}' \subset B_p$ of different types, $\mathcal{O}'^T$ does not optimally dominate $\mathcal{O}^T$ up to b.

5.1. **Analysis of Running Time.** We discuss each step of Algorithm 1 individually. We now assume that conditions (3.1) hold and so we know the algorithm terminates.

Step 1 and 2: The units of $\mathcal{O}$ are easily found and so the first part of Step 1 poses no problem. We observe that $\mathcal{O}^T = \langle v_1, v_2, v_3 \rangle$ is a 3-dimensional sublattice of $\mathcal{O} = \langle 1, u_1, u_2, u_3 \rangle$, where $\{v_1, v_2, v_3\}$ can be given explicitly in terms of $\{u_1, u_2, u_3\}$ as in the proof of Lemma 2. Hence constructing $\mathcal{O}^T$ in Step 1 and searching for short elements y_n of $\mathcal{O}^T$ in Step 2 can be done using standard lattice techniques in polynomial time.

Step 3: Several algorithms exist to compute $H_{-d_n}(X)$, see, for example, Belding, Bröker, Enge and Lauter [2] or Sutherland [17]. Under the generalised Riemann hypothesis, $H_{-d_n}(X)$ can be calculated in $\tilde{O}(d_n)$ time. It is known that $\deg(H_{-d_n}(X)) = h_{-d_n}$, the class number of the imaginary quadratic order $\mathbb{Z}[\frac{1}{2}(d_n + \sqrt{-d_n})]$.

To compute the gcd of $G(X)$ and $H_{-d_n}(X)$ in Step 3 when $\deg(G(x)) \geq 1$ we use a quasi-linear method (see, for example, Section 8.9 of Aho et al. [1] or Section 11.1 of [8]). Hence, this stage can be done in $\tilde{O}(h_{-d_n})$ operations in $\mathbb{F}_p$. By Lemma 1 of [2], we have $h_{-d_n} = O(\sqrt{d_n} \log d_n)$, and so the gcd computation can be done in $O(d_n^{0.5+\varepsilon})$ field operations.

14

As a result, we see that the limiting step of Algorithm 1 is the calculation of $H_{-d_n}(X)$, which is bounded by $O(d_n^{1+\varepsilon})$. By (3.6), $D_1, D_2, D_3, \mathrm{Nr}(x+y)$ and $\mathrm{Nr}(x-y)$ are all $O(p)$. It follows that the running time of Algorithm 1 under conditions (3.1) is $O(p^{1+\varepsilon})$ field operations. We note that under conditions (3.1), (3.7) also implies $D_3 > \frac{3}{4}p$, so if D_3 is needed we should not expect to have a faster running time.

More generally, if we no longer assume conditions (3.1), then the $O(p)$ bound on the norms is Conjecture 2. To analyse the running time of Algorithm 1 in the general case under Conjecture 2, we must bound the number of elements of $\mathcal{O}^T$ with norm less than b, i.e., the largest possible value for n in the algorithm (under conditions (3.1) we knew this was $n \leq 5$). Let B_r be the ball of radius r in $\mathbb{R}^m$ centered at the origin. A special case of a result due to Henk [10] is that for any lattice L of $\mathbb{R}^m$ with successive minima $D_1, D_2, \ldots, D_m$, it holds that $\#(L \cap B_r) < 2^{m-1} \prod_{i=1}^{m} \lfloor \frac{2r}{\sqrt{D_i}} + 1 \rfloor$. Equation (3.2) implies $D_3 \geq D_2 \geq 2\sqrt{p}$, so taking $r = \sqrt{b}$ and $b = O(p)$ gives $\#\{x \in \mathcal{O}^T \mid \mathrm{Nr}(x) < b\} = O(p^{0.5})$. This means $n \leq O(p^{0.5})$ and, since $d_i < b = O(p)$ for every $1 \leq i \leq n$ in Step 3, we obtain a running time of $O(p^{1.5+\varepsilon})$ field operations under Conjecture 2.

We remark that by itself Conjecture 1 is equivalent to the fact that Algorithm 1 halts for every maximal order $\mathcal{O}$, but it does not allow us to make any statements about its running time. We hence stress that even termination is conjectural without assuming conditions (3.1) or Conjecture 1.

Lemma 1 also tells us that $D_1 D_2 < \frac{16}{3}p$ will always hold when $j(\mathcal{O}) \in \mathbb{F}_p$. As remarked before, by finding an element $\pi \in \mathcal{O}$ such that $\pi^2 = -p$, we can tell if we are in the case when $j(\mathcal{O}) \in \mathbb{F}_p$. Hence, provided that it is computationally easier to determine the existence of such an element than to run the algorithm until $n = 5$, we could determine before running the algorithm if indeed $j(\mathcal{O}) \in \mathbb{F}_p$. Unfortunately, the number of supersingular j-invariants in $\mathbb{F}_{p^2}$ is approximately $p/12$, and of these, only $H(-4p) = O(\sqrt{p}\log p)$ lie in $\mathbb{F}_p$, where $H(-4p)$ is known as the Hurwitz class number (see, for example, Theorem 14.18 of Cox [5]). This shows that for a random maximal order $\mathcal{O} \subset B_p$, we definitely do not expect that $j(\mathcal{O}) \in \mathbb{F}_p$.

5.2. **Algorithm to match all supersingular j-invariants with all maximal orders.** In [4], Cerviño proposed an algorithm that, given a prime p, associates to every supersingular j-invariant of $\mathbb{F}_{p^2}$ the corresponding maximal order type of B_p. This is different to Algorithm 1 in that it deals with all j-invariants at once. Cerviño states that his algorithm has running time $\tilde{O}(p^{2.5})$ operations but no explanation for this is given in the paper and, as far as we can tell, the algorithm he presents is actually at best $\tilde{O}(p^4)$ field operations. To recall, Cerviño computes, on one side, a list of all $O(p)$ maximal orders and, for each such order $\mathcal{O}$, the set $\Gamma(\mathcal{O}) = \{(\mathrm{Tr}(\alpha), \mathrm{Nr}(\alpha)) : \alpha \in \mathcal{O}, \mathrm{Nr}(\alpha) = O(p)\}$. On the other side he computes a list of all $O(p)$ supersingular elliptic curves and, for each, the set $\Delta(E) = \{(\mathrm{Tr}(\phi), \deg(\phi)) : \phi \in \mathrm{End}(E), \deg(\phi) = O(p)\}$. Computing $\Gamma(\mathcal{O})$ appears to require running over the $O(p^2)$ elements in the $\mathbb{Z}$-module of rank 4, hence requiring $O(p^2)$ work, at best. Cerviño suggests to compute $\Delta(E)$ using Vélu's formulae (and this seems to require $O(p^{3+\varepsilon})$ field operations), but one can probably improve this to $O(p^{2+\varepsilon})$ operations using evaluated modular polynomials $\Phi_d(j(E), y) \in \mathbb{F}_p[x]$, computed using Sutherland's algorithm [18]. Hence, it seems possible to improve Cerviño's algorithm so that it requires $O(p^{3+\varepsilon})$ field operations.

We propose an alternative algorithm to solve this problem. The main idea of our method is to replace isogeny computations, for a very large set of isogenies, by gcds of Hilbert class polynomials. This leads to a complexity of $O(p^{2.5+\varepsilon})$ field operations.

If we consider the sub-problem of matching supersingular curves over $\mathbb{F}_p$ with their maximal orders, it seems that Cerviño's algorithm can be adapted to handle this case with complexity $O(p^{2.5+\varepsilon})$ field operations. Our method for this case has the improved complexity $O(p^{1.5+\varepsilon})$.

Cerviño's proof that the algorithm halts within a bounded running time uses a result of Schiemann (Theorems 4.4 and 4.5 of [15]) that two ternary forms with equal theta series are integrally equivalent. In our case, this translates to: if $\mathcal{O}^T$ and $\mathcal{O}'^T$ represent the same integers with the same multiplicity, then it follows that $\mathcal{O}^T \sim \mathcal{O}'^T$, and hence by Lemma 5, we have that $\mathcal{O}$ and $\mathcal{O}'$ are of the same type. Furthermore, Schiemann gives a bound b in terms of the successive minima D_1, D_2 and D_3 of $\mathcal{O}^T$, such that if $\mathcal{O}^T$ and $\mathcal{O}'^T$ represent all integers $k \leq b$ with the same multiplicity, then indeed $\mathcal{O}$ and $\mathcal{O}'$ are of the same type. For our purposes we may take $b = 3D_3$, which gives $b \leq 6p$ using (3.6), although much better bounds are given in Schiemann's general result.

It is not difficult to see that $\mathcal{O}^T$ and $\mathcal{O}'^T$ represent the same integers with the same multiplicity if and only if they optimally represent the same integers with the same optimal multiplicity. This is because every

representation $x \in \mathcal{O}^T$ of $k \in \mathbb{Z}$ can be decomposed uniquely as $x = cy$, where $y \in \mathcal{O}^T$ is optimal and c is a positive integer. More specifically, we have the following:

Lemma 13. *For any bound $b > 0$, it holds that $\theta_{\mathcal{O}^T}(k) = \theta_{\mathcal{O}'^T}(k)$ for all $k \leq b$ if and only if $\theta'_{\mathcal{O}^T}(k) = \theta'_{\mathcal{O}'^T}(k)$ for all $k \leq b$.*

We now present our alternative to Cerviño's algorithm in the general case of all supersingular curves over $\mathbb{F}_{p^2}$.

Algorithm 2

Input: Prime $p > 2$.

Output: The list of pairs $(\mathcal{O}_1, K_1(X)), \ldots, (\mathcal{O}_{t_p}, K_{t_p}(X))$, where t_p is the type number of B_p, and for all $1 \leq i \leq t_p$, $\mathcal{O}_i$ are representatives of the distinct maximal order types of B_p, and $K_i(X)$ is the minimal polynomial of the supersingular j-invariant(s) $j(\mathcal{O}_i)$.

Procedure:
  (1) For all $1 \leq i \leq t_p$, compute a $\mathbb{Z}$-basis of $\mathcal{O}_i$ and $\mathcal{O}_i^T$, find the successive minima D_1^i, D_2^i and D_3^i of $\mathcal{O}_i^T$, and set $\mathbf{D}_i = 0$.
  (2) For every $1 \leq i \leq t_p$ run Algorithm 1 on $\mathcal{O}_i$ up until it either halts normally or until we reach n such that $d_n > 6p$. If Algorithm 1 halted normally, let $K_i(X)$ be its output, store the pair $(\mathcal{O}_i, K_i(X))$, and set $\mathbf{D}_i = 1$. Otherwise let $G_i(X)$ be the current polynomial after Step 3 of Algorithm 1, and store the pair $(\mathcal{O}_i, G_i(X))$.
  (3) For all $1 \leq i, j \leq t_p$ such that $\mathbf{D}_i = 0$ and $\mathbf{D}_j = 1$, remove from $G_i(X)$ all common factors with $K_j(X)$. If $G_i(X)$ is now either linear, or quadratic and irreducible over $\mathbb{F}_p$, let $K_i(X) = G_i(X)$ and store the pair $(\mathcal{O}_i, K_i(X))$ and set $\mathbf{D}_i = 1$.
  (4) Repeat Step 3 until $\mathbf{D}_i = 1$ for all $1 \leq i \leq t_p$. Output the list of pairs

$$(\mathcal{O}_1, K_1(X)), \ldots, (\mathcal{O}_{t_p}, K_{t_p}(X)).$$

The correctness of Algorithm 2 is guaranteed by the correctness of Algorithm 1. Furthermore Algorithm 2 is always guaranteed to halt, which may seem surprising given that the same is not true for Algorithm 1 in the general case. To see that Algorithm 2 does always halt, we define a transitive order $\preceq$ on the set of maximal order types as follows: $\mathcal{O}_i \preceq \mathcal{O}_k$ if and only if $\mathcal{O}_k$ optimally dominates $\mathcal{O}_i$ up to $6p$ (meaning that $\theta'_{\mathcal{O}_i^T}(m) \leq \theta'_{\mathcal{O}_k^T}(m)$ for all $1 \leq m \leq 6p$).

We observe that if $\mathcal{O}_i \preceq \mathcal{O}_k$ and $\mathcal{O}_k \preceq \mathcal{O}_i$, then both orders $\mathcal{O}_i$ and $\mathcal{O}_k$ represent the same integers up to $6p$ with the same optimal multiplicity, and so it follows by Schiemann [15] and Lemma 13 that they are of the same type, i.e., $\mathcal{O}_i = \mathcal{O}_k$. Hence $\preceq$ is a partial order on the set of maximal order types $\{\mathcal{O}_1, \mathcal{O}_2, ..., \mathcal{O}_{t_p}\}$.

Now consider that we have just finished Step 2 of Algorithm 2 and consider $1 \leq i \leq t_p$ such that $\mathbf{D}_i = 0$ (if $\mathbf{D}_i = 1$ for all $1 \leq i \leq t_p$ then the algorithm clearly terminates without even performing Step 3). WLOG assume $i = 1$. From the remark following Algorithm 1, we know $G_1(X)$ is square-free and so before performing Step 3 we can write

$$G_1(X) = (X - j_1)(X - j_2) \cdots (X - j_k),$$

where the j-invariants $j_1, j_2, \ldots, j_k$ are all distinct and represent at least two different maximal orders i.e., we don't have $k = 1$, nor do we have $k = 2$ and j_1, j_2 form a conjugate pair. WLOG assume that $\mathcal{O}(j_1) = \mathcal{O}_1$ i.e., j_1 is the correct j-invariant associated with $\mathcal{O}_1$, and likewise that $\mathcal{O}(j_2) = \mathcal{O}_2, \mathcal{O}(j_3) = \mathcal{O}_3$, etc..

Since the roots $j_2, j_3, \ldots, j_k$ were not removed from $G_1(X)$ when we ran Step 2, this implies that $\mathcal{O}_2, \mathcal{O}_3, \ldots, \mathcal{O}_k$ all optimally dominate $\mathcal{O}_1$ up to $6p$, i.e., we have $\mathcal{O}_1 \prec \mathcal{O}_i$ (meaning that $\mathcal{O}_1 \preceq \mathcal{O}_i$ and $\mathcal{O}_1 \not\cong \mathcal{O}_i$) for all $1 \leq i \leq k$.

Assume now that $\mathbf{D}_1$ never becomes 1 after any number of repetitions of Step 3. This implies that one of $\mathbf{D}_2, \mathbf{D}_3, \ldots, \mathbf{D}_k$ always remains 0 as well, since otherwise the roots $j_2, j_3, \ldots, j_k$ would ultimately be removed from $G_1(X)$ with enough repetitions of Step 3. WLOG assume that $\mathbf{D}_2$ always remains 0. But now the same argument applies to $\mathbf{D}_2$, and there must exist another index $1 \leq i \leq t_p$ such that $\mathcal{O}_2 \prec \mathcal{O}_i$ and that $\mathbf{D}_i$ always remains 0.

Hence we can find an ascending chain $\mathcal{O}_1 \prec \mathcal{O}_2 \prec \mathcal{O}_i \prec \ldots$ such that that $\mathbf{D}_1, \mathbf{D}_2, \mathbf{D}_i, \ldots$ all remain 0. However every ascending chain clearly has an upper bound, so let us take $\mathcal{O}_1 \prec \mathcal{O}_2 \prec \mathcal{O}_i \prec \ldots \prec \mathcal{O}_n$, where $\mathbf{D}_1, \mathbf{D}_2, \mathbf{D}_i, \ldots, \mathbf{D}_n$ all remain 0, and such that we cannot find another order $\mathcal{O}_m$ such that $\mathcal{O}_n \prec \mathcal{O}_m$ and $\mathbf{D}_m$ always remains 0. But this implies that $\mathbf{D}_n$ ultimately becomes 1 after a finite number of repetitions of Step 3, which clearly leads to a contradiction. It follows that eventually $\mathbf{D}_i$ becomes 1 for every $1 \le i \le t_p$, which is equivalent to Algorithm 2 halting with the correct output.

To analyze the running time of Algorithm 2, we start by looking at Step 2. By the same argument as in the analysis of the running time of Algorithm 1 (there under Conjecture 2) we conclude that Step 2 can be done in time $O(p^{1.5+\varepsilon})$ for every $1 \le i \le t_p$. Since t_p is approximately $p/24$, Step 2 can be done overall in time $O(p^{2.5+\varepsilon})$.

By earlier discussion and results from Cerviño [4], Steps 1, 3 and 4 can be done within this running time also. Hence the overall complexity of Algorithm 2 is $O(p^{2.5+\varepsilon})$. We stress that in contrast to Algorithm 1, Algorithm 2 is guaranteed to always halt within this running time irrespective of Conjectures 1 and 2.

Finally, we remark that Algorithm 2 can be restricted to the case when $j(\mathcal{O}) \in \mathbb{F}_p$. It is possible to enumerate in Step 1 the maximal order types $\mathcal{O}_1, \mathcal{O}_2, \ldots, \mathcal{O}_{H(-4p)}$ whose j-invariants lie in $\mathbb{F}_p$ in $O(p^{0.5+\varepsilon})$ field operations [13]. From the analysis of Algorithm 1 under conditions (3.1), we know that Step 2 of Algorithm 2 can be done in time $O(p^{1+\varepsilon})$ for every $1 \le i \le H(-4p)$. Since $H(-4p) = O(p^{0.5+\varepsilon})$, this leads to a complexity of $O(p^{1.5+\varepsilon})$ in this restricted case.

Appendix A. Two Examples

We demonstrate two examples of how Algorithm 1 runs, which were both constructed using the software package Magma [3].

Example 1. Let $p = 61$. The quaternion algebra B_{61} is spanned by $\{1, i, j, k\}$ where $i^2 = -61, j^2 = -7$ and $k = ij = -ji$.

It can be checked that

$$\mathcal{O} = \mathbb{Z} + \mathbb{Z}\left(\frac{1}{2} + \frac{1}{2}j\right) + \mathbb{Z}\left(-\frac{1}{2} - \frac{1}{14}j + \frac{1}{7}k\right) + \mathbb{Z}\left(-\frac{1}{2} + \frac{1}{2}i - \frac{3}{14}j - \frac{1}{14}k\right)$$

is a maximal order of B_{61}.

We construct $\mathcal{O}^T$ and find that its shortest element is $y_1 = j$. We set $d_1 = \mathrm{Nr}(y_1) = 7$, and

$$G(X) = H_{-d_1}(X) = H_{-7}(X) = X - 41 \in \mathbb{F}_{61}[X].$$

We conclude that the j-invariant associated to the maximal order $\mathcal{O}$ is $j(\mathcal{O}) = 41 \in \mathbb{F}_p$.

Example 2. Let $p = 20063$. The quaternion algebra B_{20063} is spanned by $\{1, i, j, k\}$ where $i^2 = -20063, j^2 = -1$ and $k = ij = -ij$. We take $\mathcal{O}$ as the maximal order in B_{20063} with $\mathbb{Z}$-basis

$$\mathcal{O} = \mathbb{Z}\left(\frac{1}{2} + \frac{1}{16}j + \frac{13615}{16}k\right) + \mathbb{Z}\left(\frac{1}{512}i + \frac{151}{4096}j + \frac{1109113}{4096}k\right)$$
$$+ \mathbb{Z}\left(\frac{1}{8}j + \frac{13615}{8}k\right) + 2048\mathbb{Z}k.$$

We construct $\mathcal{O}^T$ and begin searching through its short elements. We find

$$y_1 = \frac{11}{64}i - \frac{8323}{512}j + \frac{51}{512}k,$$

which gives

$$d_1 = \mathrm{Nr}(y_1) = 1056,$$

and

$$G_1(X) = H_{-d_1}(X) = H_{-1056}(X) \in \mathbb{F}_{20063}[X],$$

where $\deg(H_{-1056}(X)) = 16$.

Next we find

$$y_2 = \frac{67}{256}i + \frac{52101}{2048}j - \frac{85}{2048}k,$$

which gives

$$d_2 = \mathrm{Nr}(y_2) = 2056,$$

and

$$G_2(X) = \gcd(G_1(X), H_{-2056}(X)) = X^3 + 8728X^2 + 8070X + 5035 \in \mathbb{F}_{20063}[X],$$

where $\deg(H_{-2056}(X)) = 16$.

Next we find

$$y_3 = \frac{23}{256}i + \frac{85393}{2048}j - \frac{289}{2048}k$$

which gives

$$d_3 = \mathrm{Nr}(y_3) = 2300,$$

and

$$G_3(X) = \gcd(G_2(X), H_{-2300}(X)) = X^2 + 2748X + 6627 = (X - \alpha)(X - \overline{\alpha}) \in \mathbb{F}_{20063}[X],$$

where $\deg(H_{-2300}(X)) = 18$ and $\alpha, \overline{\alpha}$ form a conjugate pair.

Hence we conclude that $\mathcal{O}$ corresponds to a conjugate pair of supersingular j-invariants, $j(\mathcal{O}) = \alpha, \overline{\alpha}$ with minimal polynomial $X^2 + 2748X + 6627$ over $\mathbb{F}_{20063}$.
